Subject:

Granville Solvents Site (GSS) Removal Action

Aquifer Test Operational Plan

Dear Mr. Fredle:

Pursuant to the U.S. EPA's comments on the Draft Work Plan (October 18, 1994) in a letter dated November 8, 1994 and November 16, 1994, and as agreed in our responses to those comments provided to you November 18, 1994, the Granville Solvents Site PRP Group herein delivers the Operational Plan for the Aquifer Pumping Test. As requested by Mr. Edward Hanlon, a copy of this document will be sent to Mr. Steve Acree of the U.S. EPA.

If you have questions regarding this submittal, please call Mr. Ben Pfefferle at 614-469-3200 or Michael Raimonde at the number below.

Respectfully,

METCALF & EDDY, INC.

Gerald R. Myers

Vice President/Project Coordinator

1.0 INTRODUCTION

The purpose of this Operational Plan is to provide a description of the operational procedures for the Aquifer Pumping Test during the Removal Action at the Granville Solvents Site (GSS). This description is intended to augment the information provided in the Work Plan for the Removal Action dated October 19, 1994 and revised November 18, 1994.

The Operational Plan is separated into four major sections: Section 1 - Introduction, Section 2 - General Aquifer Pumping Test Design, Section 3 - Groundwater Monitoring Well Sampling Procedures, and Section 4 - Discharge Requirements and Expected Discharge Concentrations.

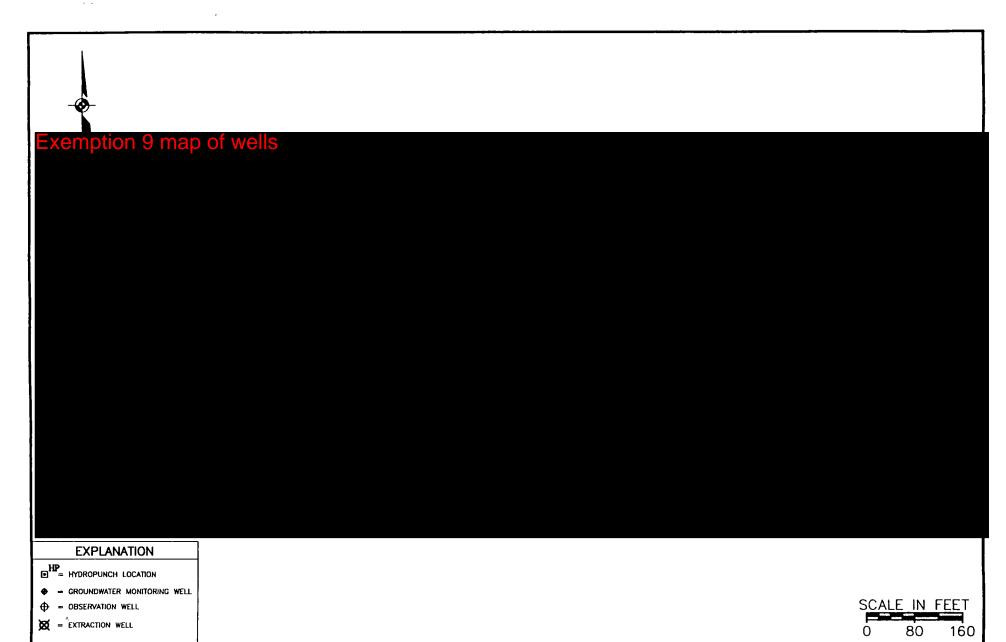

2.0 GENERAL AQUIFER PUMPING TEST DESIGN

The aquifer test will be conducted in three segments: establishing baseline water level trend, short term aquifer pumping test, and long term aquifer pumping test. Each of these segments are described below. The aquifer test will be conducted by pumping extraction wells GSS-EW1 and GSS-EW2 as described below. Observation wells for the test will include GSS-P1, GSS-P2, MW-8D, MW-7D, GSS-MW1, GSS-MW2, and PW-1 (Figure 1).

2.1 ESTABLISHING BASELINE WATER LEVEL TREND

Approximately four days prior to the aquifer test, water levels will be measured and recorded once in all observation wells to be used in the test. In addition, water levels will be measured and recorded in the test well GSS-EW2, and observation wells GSS-P1, GSS-P2, and MW-7D using pressure transducers and a data logger. The frequency of measurement for these four wells will be approximately once every sixty minutes for the four days prior to the test. The rate and duration of pumping of Village production wells PW-2 and PW-3 during this time period will be obtained from the Village of Granville, if available. Data collected before the pumping test will be used to produce potentiometric maps to further define background hydraulic gradients and flow directions. These will be compared to data collected during pumping to evaluate the pumping influence.

Barometric pressure will also be recorded for four days before the test and during the test period. A barometer will be placed in one of the wells above the water level. Barometric, precipitation, and other meteorological data will also be obtained from a local weather station. The barometric data will be used

Metcalf & Eddy

GRANVILLE SOLVENTS SITE
PUMPING TEST LAYOUT
GRANVILLE, OHIO

Project Number 016688-0006 File Name Figure

6688–1 1

to determine if changes in atmospheric pressure influence water levels in the aquifer. If so, the pumping test data will be adjusted to account for barometric effects.

2.2 SHORT TERM AQUIFER PUMPING TEST

A short-term pumping test will be conducted by pumping extraction well GSS-EW2 at a constant rate for a period of 72 hours. The purpose of the short term aquifer test is to determine the aquifer properties in the vicinity of the test well under time-dependent conditions. The following sections describe the basic procedures that will be followed for this test.

2.2.1 Water Level Measurements

Prior to the start of the short term aquifer test, water levels will be measured using a weighted surveyor's steel tape and water sensing paste in the test well GSS-EW2 and the observation wells GSS-P1, GSS-P2, MW-8D, MW-7D, GSS-MW1, GSS-MW2, and PW-1. Use of the weighted tape is the preferred method for measuring water levels to the greatest accuracy. The water elevation of Raccoon Creek will also be measured at the surveyed location on the Cherry Street overpass. If practical, water levels will be measured and recorded for the other existing monitoring wells on the Site.

2.2.2 Test Well

The short term aquifer test will be conducted by pumping extraction well GSS-EW2, currently under construction. The boring log for the pilot hole is shown in Figure 2. GSS-EW2 is designed with telescoping well construction extending from the surface (916 feet amsl) to an elevation of 824 feet amsl (a depth of 92 feet). The well is designed to be constructed of 10-inch inside diameter black iron pipe extending from the surface to an elevation of 874 feet amsl. A telescoping well screen will extend from 874 feet amsl to 824 feet amsl (42 to 92 feet). The screen will be 304 stainless steel wire wrapped with 0.04-inch slot opening (custom manufactured from Cook Well Screen). The screen design is based on a grain size determination by standard sieve analysis of a sample of the aquifer collected from a pilot hole drilled at the location of GSS-EW2 (Figure 3). The slot size was chosen to optimize well performance and allow retention of 50% of the formation material.

The well is designed to provide production of 250 gallons per minute (gpm). However, during the short term aquifer pumping test, GSS-EW2 will be pumped at a constant rate of approximately 100 gpm. The

well will be outfitted with a submersible pump constructed primarily of stainless steel and capable of pumping 250 gpm under the assumed pressure head conditions. The pump will be placed in a section of blank casing in the bottom ten feet of the well, below the well screen.

The extraction rate will be measured using an in-line flow meter at a frequency of once every hour for the initial part of the test and periodically thereafter. The meter will also allow measurement of the cumulative volume pumped during the test.

2.2.3 Observation Well Network

The observation well network will consist of the following wells: GSS-P1, GSS-P2, MW-8D, MW-7D, GSS-MW1, GSS-MW2, and PW-1 as shown on Figure 1.

Piezometers

Two piezometers were installed in the vicinity of test well GSS-EW2 (GSS-P1 and GSS-P2) to be used as observation wells during the short term aquifer pumping test. Observation well GSS-P1 was installed 20 feet northeast of GSS-EW2 and GSS-P2 was installed 40 feet southeast of GSS-EW2. The borings in which these wells were installed were drilled using 4.25-inch inside diameter hollow stem augers. The borings were logged by using two-inch inside diameter two-foot long split spoon samplers to collect soil cores on five-foot centers (Figures 4 and 5). The water table was encountered at an approximate elevation of 898 feet amsl. Each boring was extended to an elevation of approximately 852 feet amsl, approximately 45 feet below the water table.

Each observation well was constructed using threaded two-inch inside diameter schedule 40 polyvinyl chloride (PVC) riser casing and a twenty foot long PVC well screen with 0.01-inch factory cut slot openings (Figures 6 and 7). The wells were installed by placing the well riser casing and screen inside the augers and adding 20/40 clean silica sand while progressively removing the augers, allowing the sand to fill the annular space between the well screen and the natural aquifer material. The sand was added to an elevation approximately two feet above the top of the well screen. Bentonite pellets were placed on top of the filter pack in six-inch lifts to a total thickness of no less than two feet. The bentonite was allowed to hydrate prior to the placement of a bentonite cement

grout (mixture: 94 pounds of Type 1 Portland Cement, 3% powdered bentonite, and 7 gallons of potable water) using a side discharging tremie pipe placed at a depth immediately above the bentonite annular seal. The well was finished flush to the ground with a flush-mount protective casing.

Monitoring Wells

One groundwater monitoring (GSS-MW2) well has been installed 100 feet southeast of GSS-EW2 and 150 feet south of monitoring well MW-8. This well will be used as an observation well during the short term aquifer pumping test. The boring was drilled and logged and the well was constructed as described above for the piezometers. Figures 8 and 9 show the boring log and well construction. The water table was encountered at an approximate elevation of 898 feet amsl. The boring was extended to an elevation of approximately 883 feet amsl, 15 feet below the water table.

A second groundwater monitoring well, GSS-MW1 will be installed, pending access approval by the land owner, approximately 100 feet north-northeast of monitoring well MW-8. The well will be installed in the same manner as GSS-MW2, described above.

In addition to groundwater monitoring wells GSS-MW1 and GSS-MW2, previously installed monitoring wells MW-7D and MW-8D will be used during the short term aquifer pumping test as observation wells. It is recognized that partial penetration of the well screen of these monitoring wells will limit their use during this test.

Other Wells

Village of Granville production well PW-1 and groundwater extraction well GSS-EW1 will also be used as observation wells during the short term aquifer pumping test. Well PW-1 extends from the ground surface to an elevation of approximately 800 feet amsl and is screened from 835 feet amsl to the total depth of the well, 100 feet. PW-1 has been temporarily taken out of service as a result of the removal action. The well design for GSS-EW1 is described below in the description of the long term aquifer pumping test.

2.2.4 Data Collection Procedures

Prior to testing, water levels will be measured and recorded in all wells participating in the test. Water level measurements will be continuously recorded using pressure transducers and a data logger in the test well and in observation wells GSS-P1, GSS-P2, MW-7D, MW-8D, GSS-MW1, GSS-MW2, and PW-1. Test measurements will be taken on a logarithmic cycle (frequent measurements initially and less frequent measurements over time) with the longest period between measurement of approximately 60 minutes. For wells not outfitted with continuous reading instruments, measurements will be made periodically throughout the test, generally once every hour for the first 10 hours, where accessible, and periodically thereafter. For instrumented wells, check measurements by hand will be made frequently, generally once every hour, in the first 8 hours and periodically thereafter. Barometric pressure will also be recorded using a transducer and data logger. The test will target a total pumping time of 72 hours.

The water produced from GSS-EW2 will be sampled for laboratory analysis near the start of the test. The samples will be analyzed for Target Compound List (TCL) volatile organic compounds (VOC's) using USEPA Method 524.2 and the metals with applicable discharge limits (see section 4.0). All water removed from GSS-EW2 during the short duration test will be pumped directly into Raccoon Creek. Sampling of the effluent and handling of the water during the long term test are discussed below.

2.3 LONG TERM AQUIFER PUMPING TEST

Immediately following the 72 hours of pumping in the short term test, a long term aquifer test will commence. The objective of the long term test is to monitor the influence of long term, combined pumping of extraction wells GSS-EW1 and GSS-EW2. A preliminary groundwater flow model presented in the November 18, 1994 Work Plan concluded that pumping of the extraction wells at 100 gpm each would be adequate to control the hydraulic gradient such that the plume would not move toward the Village production wells. Data from both the short and long term tests will be used to evaluate this conclusion.

Well GSS-EW2 will continue to be pumped at the constant rate of 100 gpm for duration of the long term test. The long term test will begin by initiating pumping of well GSS-EW1 at a constant rate of 100 gpm. The duration of the long term test will be 27 days with both extraction wells pumping at 100 gpm. This will result in pumping of GSS-EW2 for a cumulative 30 days.

Extraction well GSS-EW1, is also currently under construction. GSS-EW1 is designed with telescoping well construction extending from the surface (916 feet amsl) to an elevation of 815 feet amsl. The well will be constructed of 10-inch inside diameter black iron pipe extending from the surface to an elevation of 880 feet amsl (36 feet). A telescoping well screen will extend from 880 feet amsl to 860 feet amsl (36 to 56 feet). Below the upper screen, casing will extend from 860 feet amsl to 845 feet amsl (56 to 71 feet). A second screen will be placed between 845 feet amsl to 825 feet amsl (71 to 91 feet). The well screens and separating casing will consist of 304 stainless steel. The screen will be wire wrapped with 0.04-inch slot opening (custom manufactured from Cook Well Screen).

GSS-EW1 is located within the source area where groundwater is most highly impacted. As described in the November 18, 1994 Work Plan, the highest constituent levels are present in the relatively shallow groundwater near this location. To avoid drawing this water deeper into the aquifer, pumping of GSS-EW1 will take place from the upper screen section (36 to 56 feet). A submersible pump, capable of pumping 100 gpm and constructed primarily of stainless steel, will be set slightly below the upper screen. A packer will be placed in the blank casing section below the upper screen and below the pump to isolated the lower portion of the well. The lower screen will be installed to allow for pumping of the lower portion of the aquifer in the future, if necessary. The primary reason for installing the lower screen at this time is to reduce overall costs if it is determined in the future that deep pumping is needed.

During the long term test, the effluent from wells GSS-EW1 and GSS-EW2 will be combined and treated through an air stripper before discharging to Raccoon Creek. Pre-treatment and post-treatment water samples will be collected for laboratory analysis once each week. The samples will be analyzed for Target Compound List (TCL) volatile organic compounds (VOC's) using USEPA Method 524.2 and the metals with applicable discharge limits (see section 4.0).

The data collection procedures during the long term pumping test will be similar to those described above for the short term test.

2.4 PUMPING TEST DATA EVALUATION

Water level data obtained during the short term test will be analyzed to determine the properties of the aquifer in the vicinity of the test well. The data will be evaluated by both time-drawdown and distance-drawdown methods. Appropriate, standard methods based on the Theis equations and modifications to

the Theis equations will be employed. Corrections for partial penetration or dewatering will be made if needed, based on review of the data.

Data from both the short and long term tests will be plotted to produce potentiometric maps for various points in time. These maps will allow visual representation of the influence of pumping on the groundwater flow directions. The radius of influence of the pumping wells will be determined based on the aquifer properties and construction of potentiometric maps and/or flow nets. This information will allow further definition of the pumping rates required to control the hydraulic gradient to meet the performance objectives of the system.

3.0 GROUNDWATER MONITORING WELL SAMPLING PROCEDURES

Sampling of monitor wells will take place during the operation of the groundwater extraction system. A quality assurance/quality control (QA/QC) plan discussing sampling and analysis of groundwater for the Granville Solvents Site has been previously submitted and approved. Future sampling will follow the approved plan.

Before sampling, the total well depth and depth to water will be measured with a clean water level indicator. The volume of water in the well will be calculated based on the total height of the water column in the well and the well radius. A minimum of three well volumes will be purged from the well before sampling. Purging will continue until the field-measured parameters (pH, specific conductance, and temperature) have stabilized. The wells will be purged and sampled using bottom-discharging, stainless steel bailers fitted with a sampling stopcock. The monitor well samples will be analyzed for Target Compound List (TCL) volatile organic compounds (VOC's) using USEPA Method 524.2.

4.0 DISCHARGE REQUIREMENTS AND EXPECTED DISCHARGE CONCENTRATIONS

The discharge requirements and expected discharge concentrations for discharge of water to Raccoon Creek and discharge to the air from the water treatment system are listed on Tables 1 and 2, respectively.
